I Introduction

At the present time there are many license plate recognition (LPR) solutions in the market, designed to work in areas such as: traffic control and monitoring, parking access, vehicle management, detection of security violations and so forth. The best LPR engines support many countries, all license plate layouts, char sets, and some of them feature a 98% recognition rate or greater at recognition speeds of less than 10 ms per frame. Not surprisingly, this superior performance generally comes at a price; the best engines can cost thousands of dollars per runtime license.

On the other hand, there are consumer oriented applications that would benefit from LPR but the cost of a high end LPR engine is too high for their segment. This is where SimpleLPR 2 comes in. SimpleLPR 2 is a royalty free low end LPR engine directed to price sensitive applications that can cost an order of magnitude less than its high end counterparts, at the expense of a limited number of supported countries and lower accuracy; the typical recognition rate is about 90% although as new releases appear this number is expected to improve. For applications that can trade some recognition accuracy for an affordable price SimpleLPR 2 is an option that should be considered.

From a developer’s perspective, SimpleLPR 2 main design goal is integration and deployment simplicity. Hence, SimpleLPR 2 runtime can be redistributed along with third party applications by just x-copying a few dll files that do not require COM registration. SimpleLPR2.dll is dual, in addition to a C++ interface for native C++ applications it also exports a .NET object model that can be directly used from VB or C#. The current version supports more than 30 countries (see supported countries and limitations). It can read 24 bit RGB or 8 bit grayscale images from JPEG, TIFF, BMP or PNG files, or from a memory buffer.

This guide contains both the product description and documentation for developers. In the following sections all required information on how to integrate SimpleLPR 2 into a third party application is provided.
2 Supported Countries and Limitations

The current version can read license plates from the countries listed below, provided that they are in good condition; namely the license plates should be crisp, readable, without occlusion, bumps or scratches. In addition, images supplied to the SimpleLPR 2 engine should portray the license plate as viewed from a frontal angle, and the height of the license plate characters should be 20 pixel or taller.

Irrespective of complying with the above constraints, in general not all valid license plates from a specific country can be recognized. The level of support varies from country to country as it can be seen below.

2.1 License Plates of Algeria

Standard license plates in the formats described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Algeria are supported.

2.2 License Plates of Australia

General series standard issue license plates in the formats described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Australia are supported.

2.3 License Plates of Belgium

Both single line and square license plates in the 1973 format and newer are supported, as described in the article http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Belgium.

2.4 License Plates of Bolivia

Plates complying with the standard described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Bolivia are supported.

2.5 License Plates of Brazil

Both single line and square license plates in the current 1990 format are supported, as described in the article http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Brazil.

2.6 License Plates of Bulgaria

Standard single line and square license plates in the 1993 format described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Bulgaria are supported. Trailer, diplomatic, and military vehicles are not supported.

2.7 License Plates of Canada

For designs featuring a non plain background the use of IR illuminators and filters is recommended.
2.8 License Plates of Cape Verde
Standard license plates in the formats described in

2.9 License Plates of Chile
Plates complying with the standard described in

2.10 License Plates of Colombia
Standard license plates in the formats described in

2.11 License Plates of Croatia
Standard single line and square license plates in the format described in
Diplomatic and military vehicles are not supported.

2.12 License Plates of Cuba
Standard license plates in the new 2013 specification described in

2.13 License Plates of the Czech Republic
Single line and square license plates following the 2001 specifications or newer are supported, as described in

2.14 License Plates of Denmark
Standard single line and square license plates in the format described in
Diplomatic and military vehicles are not supported.

2.15 License Plates of Ecuador
Standard license plates in the formats described in

2.16 License Plates of El Salvador
Standard single line license plates are supported.
2.17 License Plates of Estonia
Plates complying with the standard described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Estonia are supported.

2.18 License Plates of France
Single line and square license plates following the general or the newer 2009 specifications are supported, as described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_France. Military and diplomatic plates are not supported.

2.19 License Plates of Germany
The article http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Germany is the source where the syntax rules for German license plates verification have been obtained from. Specifically, the current 1994 format is supported for private and public vehicles as described in the article. The list of valid district codes has been extracted from http://de.wikipedia.org/wiki/Liste_der_Kfz-Kennzeichen_in_Deutschland. Trailer, diplomatic, motorcycle and military vehicles are not supported.

Square license plates are only partially supported. Due to a limitation in the current engine only license plates with two or three letter district codes can be read. This shortcoming will be addressed in the future.

2.20 License Plates of Greece
Standard single line and square license plates in the 1972 and newer formats, as described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Greece, are supported. Diplomatic and military vehicles are not supported.

2.21 License Plates of Guatemala
Standard single line license plates are supported.

2.22 License Plates of Honduras
Standard single line license plates are supported.

2.23 License Plates of Hungary
Standard single line license plates in the 1990 and newer formats, as described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Hungary, are supported. Square two line license plates are not supported yet.

2.24 License Plates of India
Standard single line and square license plates in the 2000 and newer formats, as described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_India, are supported. Diplomatic and military vehicles are not supported.
2.25 License Plates of Ireland

2.26 License Plates of Israel

Standard single line and square license plates complying with the format described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Israel are supported. Police, diplomatic and military vehicles are not supported.

2.27 License Plates of Italy

Standard single line and square license plates in the 1994 and newer formats, as described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Italy, are supported. Diplomatic and military vehicles are not supported.

2.28 License Plates of Kenya

2.29 License Plates of Latvia

Standard single line and square license plates in the format described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Latvia are supported. Diplomatic and military vehicles are not supported.

2.30 License Plates of the Netherlands

All standard single line and square license plates in the 1978 and newer formats are supported, as described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_the_Netherlands. Military and diplomatic plates are not supported.

2.31 License Plates of Norway

Standard single line and square license plates in the format described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Norway are supported. Diplomatic and military vehicles are not supported.

2.32 License Plates of Peru

Plates complying with the standard described in http://www.carsandplates.com/pe.html are supported.
2.33 License Plates of Poland

2.34 License Plates of Portugal

2.35 License Plates of Romania

2.36 License Plates of Singapore
All standard single line and square license plates issued after 1994 are supported, as described in [http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Singapore](http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Singapore). The checksum code is not verified. Military and diplomatic plates are not supported.

2.37 License Plates of Slovakia
All standard single line and square license plates in the 1997 and newer formats are supported, as described in [http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Slovakia](http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Slovakia). Military and diplomatic plates are not supported.

2.38 License Plates of Spain
Private and public car license plates issued after 1980 are supported, as described in [http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Spain](http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Spain). Trailer, diplomatic, motorcycle and military vehicles are not supported. On the other hand, square license plates are fully supported.

2.39 License Plates of Sweden
2.40 License Plates of Switzerland

Plates complying with the standard described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Switzerland are supported.

2.41 License Plates of Turkey

The current version supports License plates complying with the formats described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Turkey. Military and diplomatic plates are not supported.

2.42 License Plates of the United Kingdom

SimpleLPR 2 can read private and public license plates from Great Britain issued after 1983. See http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_the_United_Kingdom. Trailer, diplomatic, motorcycle and military vehicles are not supported. Square license plates issued after 2001 are supported.

2.43 License Plates of Venezuela

Standard license plates in the formats described in http://www.carsandplates.com/ve.html are supported.

2.44 License Plates of Vietnam

License plates complying with the formats described in http://en.wikipedia.org/wiki/Vehicle_registration_plates_of_Vietnam are supported. Military and diplomatic plates are not supported.
3 Prerequisites, Installation and Deployment

3.1 Prerequisites

SimpleLPR 2 requires a computer running a Windows XP or newer operating system and the MSXML 6.0 XML parser. From a hardware standpoint, the only requirement is a CPU supporting SSE2 extensions.

Any 5 year old or newer computer kept regularly updated with Microsoft’s patches and service packs should already meet the above requirements. Nevertheless, if required the above software prerequisites can be downloaded from Microsoft.

2. To check if a specific processor supports SSE2 http://en.wikipedia.org/wiki/SSE2

3.2 Installation

The SimpleLPR 2 SDK is shipped in a MSI installer. It creates the SDK file structure and automatically takes care of the dependencies: if needed it will install the Visual Studio 2010 C++ runtime. It will also verify that MSXML 6.0 is installed and check for SSE2 extensions, prompting the user if any of them are not available.

Upon installation SimpleLPR 2 operates in evaluation mode, which lasts for 30 days. Once the evaluation period terminates SimpleLPR 2 will stop working, unless a valid product key is supplied.

3.3 Deployment

SimpleLPR 2 can be deployed by simply copying the contents of the bin directory in the SDK to the same folder as the application executable. If the target application is using the .NET classes exposed by the SimpleLPR2.dll assembly it is important to copy also the contents of the native folder. Two considerations to be borne in mind are

1. SimpleLPR 2 cannot operate in evaluation mode when redistributed. The application has to supply a product key.
2. The installer of the third party application must ensure that all prerequisites are met.
4 License Plate Recognition with SimpleLPR 2

This section describes the major steps to integrate SimpleLPR 2 into an application. In each stage both C++ and .NET flavors are examined individually. .NET sample code is presented in C#.

4.1 SimpleLPR 2 Instantiation

This step comprises the tasks of loading SimpleLPR2 into the application process space and creating an instance of the SimpleLPR engine.

Native C++ Applications

For native C++ applications a native dll is provided with name SimpleLPR2_native.dll, which exports a public function, Setup that works as a factory method of ISimpleLPR objects. The prototype of the Setup function is defined in include/SimpleLPR.h

\[
\text{ISimpleLPR} \ast \_stdcall \text{Setup}() \text{ throw ()};
\]

Although a .lib file is provided for SimpleLPR2_native.dll it is advised to perform the binding programmatically by means of either the LoadLibrary or LoadLibraryEx calls. Once a pointer to the Setup function is acquired, it can be used to create an instance of the SimpleLPR 2 engine, encapsulated in the ISimpleLPR interface. The following code snippet illustrates this.

\[
\text{// Load the SimpleLPR dll}
\text{HMODULE hLib = LoadLibraryEx( L"SimpleLPR2.dll", NULL, 0 );}
\text{if ( hLib == NULL )}
\text{\_\_ \_ Handle error condition}

\text{// Get the entry point to the Setup function}
\text{SimpleLPRSetupFunc pfnSetup = (SimpleLPRSetupFunc)::GetProcAddress( hLib, "Setup" );}
\text{if ( pfnSetup == 0 )}
\text{\_\_ \_ Handle error condition}

\text{// Create an instance of the SimpleLPR engine}
\text{ISimpleLPR \_pLPR = (*pfnSetup)();}
\text{if ( pLPR == NULL )}
\text{\_\_ \_ Handle error condition}

\_\_ \_ Do your stuff

\text{pLPR->release(); // Delete engine}

.NET Applications

A .NET assembly with name SimpleLPR2.dll is provided, which dispatches user calls to either the 32 bit or 64 bit version of SimpleLPR2_native.dll depending on the calling assembly mode. Once added to the project as an assembly reference an instance of the SimpleLPR 2 engine can be created using the Setup static factory method in the SimpleLPR class.

\[
\text{ISimpleLPR lpr = SimpleLPR.Setup();}
\]
4.2 Engine Configuration

Firstly, depending on whether SimpleLPR 2 is to be used in evaluation mode or not, a valid product key must be provided. The product key can be supplied either from a file or from a memory buffer. As it contains personal data from the purchaser in readable form the second method is preferred.

Then, the user must decide what countries are to be enabled and what are their relative weights. These weights are used to break ties in the case that two or more candidates from different countries are equally feasible. The SimpleLPR 2 engine exports methods to assign each country a weight equal or greater than 0. Setting a weight equal to 0 effectively disables a country. Those weights are later normalized to the [0...1] range. As license plate recognition goes on, chances are that discovered groups of text and numbers match the syntax verification rules of more than one country. The ‘goodness’ index of each license plate candidate is multiplied by the normalized country weight and the best candidate is kept.

Enabling multiple countries is discouraged as it has an impact on reliability. In case this cannot be avoided, the relative country weights should be set equal to the expected ratio of vehicles from each country.

The samples below show how to set the product key and configure country weights in each development platform.

Native C++ Applications

```cpp
// Set the product key
bool bOk = pLPR->productKey_set( L"productkey.xml" );
if ( ! bOk )
    ... \\ Handle error condition

// Enable Germany, disable Spain and United Kingdom
bOK = pLPR->countryWeight_set( L"Germany", 1.f )
if ( ! bOk )
    ... \\ Handle error condition
bOK = pLPR->countryWeight_set( L"Spain", 0.f )
if ( ! bOk )
    ... \\ Handle error condition
bOK = pLPR->countryWeight_set( L"UK-GreatBritain", 0.f )
if ( ! bOk )
    ... \\ Handle error condition

// Apply changes
bOK = pLPR->realizeCountryWeights();
if ( ! bOK )
    ... \\ Handle error condition
```
.NET Applications

// Set the product key
lpr.set_productKey(“productkey.xml”);

// Enable Germany, disable Spain and United Kingdom
lpr.set_countryWeight(“Germany”, 1.0f);
lpr.set_countryWeight(“Spain”, 0.0f);
lpr.set_countryWeight(“UK-GreatBritain”, 0.0f);

// Apply changes
lpr.realizeCountryWeights();

4.3 License Plate Recognition

Once the SimpleLPR 2 engine has been properly configured the remaining step is creating an instance of an IProcessor object to perform license plate recognition. Since IProcessor is not thread safe, each working thread involved in LPR should keep its own instance of IProcessor.

An IProcessor can read and process images from a file, in either RGB or grayscale JPEG, TIFF, PNG and BMP formats or, alternatively, it can process images directly from a memory buffer. In the later case the image must be either RGB 24-bit or grayscale 8-bit. The output of the ANPR methods is a list of license plate candidate objects. Each object having the license plate text in Unicode string form, the global confidence index, and the bounding box and confidence value of all individual elements in the license plate.

The license plate text is formatted according to the rules of each specific country so spaces or hyphens can be added to separate groups of text and numbers. The returned confidence index is the direct output from the OCR classifier. It ranges from 0 to 1, but it should not be regarded as a probability. Depending on the license plate font and the specific glyph its operating range can vary significantly. As a result, care should be taken when setting thresholds to discard weak candidates. The rule of thumb is that very low values almost always point to an unreliable detection, and values close to one imply a safe candidate. Unfortunately, in most cases the confidence values lay in no one’s land and nothing can be decided. Future versions of the product will try to address this problem. Finally, the global candidate confidence index is taken as the lowest value of all individual elements in the license plate.

Native C++ Applications

// Create processor
IProcessor *pProc = pLPR->createProcessor();
if( pProc == NULL )
{   // Handle error condition
    ...
}

// Process source file
ICandidates *pCds = pProc->analyze( L"vehicle.jpg", 120 /* max char height */ );
if( pCds == NULL )
{   // Handle error condition
    ...
}
if ( pCds->numCandidates_get() == 0 ) std::wcout << L"No license plate found" << std::endl;
else
{
    std::wcout << pCds->numCandidates_get() << L" license plates found:" << std::endl;
}
// Iterate over all candidates
for ( _SIZE_T i = 0; i < pCds->numCandidates_get(); ++i )
{
    ICandidate *pCd = pCds->candidate_get( i );
    if( pCds == NULL )
        \ \ Handle error condition

    std::wcout << L"Candidate " << i + 1 << std::endl;
    std::wcout << L"Text: " << pCd->text_get() << L" , confidence: ";

    std::wcout << pCd->confidence_get() << L", Light background " << pCd->
brightBackground_get() << std::endl;
    std::wcout << L"Elements: " << std::endl;

    // Iterate over all elements
    for ( _SIZE_T j = 0; j < pCd->numElements_get(); ++j )
    {
        Element e;
        pCd->element_get( j, e );

        std::wcout << L"Glyph: " << e.glyph << L", confidence: " <<
        e.fConfidence;
        std::wcout << L", left: " << e.boundingBox.left << L", top: " <<
        e.boundingBox.top;
        std::wcout << L", width: " << e.boundingBox.width << L", height: " <<
        e.boundingBox.height;
        std::wcout << std::endl;
    }
    pCd->release();
}

// Cleanup
pCds->release();
pProc->release();

.NET Applications

// Create Processor
IProcessor proc = lpr.createProcessor();

// Process source file
List<Candidate> cds = proc.analyze( "vehicle.jpg", 120 120 /* max char
height */ );
if (cds.Count > 0)
{
    // Iterate over all candidates
    foreach ( Candidate cd in cds )
        Console.Write(" [{0}, {1}]", cd.text, cd.confidence);
    Console.WriteLine();
}
else
    Console.WriteLine("Nothing detected");
4.4 Considerations on Error Handling and Resource Management

For the sake of simplicity, the subject of error handling has been deliberately omitted in the sample code above. In addition, the reference counting scheme implemented in the C++ interface deserves some discussion.

Native C++ Applications

Most C++ developers consider that exceptions are the best way of dealing with error conditions in C++. However, exceptions are compiler vendor dependant and are not appropriate for a public interface exported from a DLL. For this reason, SimpleLPR 2 relies on the old technique of returning error codes and maintaining a per-thread error state. Every method in the C++ interface returns either a boolean (true meaning success) or a NULL value in case that the method is expected to return a pointer.

Once an error condition has been determined, further error information can be queried by means of the lastError_get() method. Each thread keeps its own copy of the last_error variable. The following code snippet shows how the error state can be obtained.

```cpp
SimpleLPR2_Native::IErrorInfo *pErr = pLPR->lastError_get();
if ( pErr != NULL )
{
    pErr->release(); // Free object
}
```

On the subject of resource management, the standard way of de-allocating objects in C++ is using the delete operator. On the other hand, the golden rule of any DLL returning C++ objects is that resources must be allocated and de-allocated inside the DLL. A way to accomplish it is making objects delete themselves. The reference counting idiom does this; each object keeps track of how many references point to it. When this counter reaches 0 the object deletes itself. Thus, all objects exported in the C++ interface derive from IReferenceCounted. This interface has two methods, addRef, which increments objects reference counter by one, and release, which decrements it. All objects returned by the SimpleLPR 2 factory methods have their reference counter set to 1 and a call to their release method actually destroys them.

.NET Applications

As usual, .NET makes life easier for developers. Error conditions are dealt with the use exceptions, which is the standard way in .NET. Likewise, resource management is not an issue here as the garbage collector takes care of this subject.
5 C++ Interface Reference

The file `include\SimpleLPR.h` contains all class declarations and function prototypes described in this section. All members are declared under the `SimpleLPR2_Native` namespace.

5.1 Functions

5.1.1 Setup

```c
SIMPLELPRI API ISimpleLPR * SIMPLLELPRI_CALL Setup() throw ();
```

**Description:** This is the only function exported by SimpleLPR2.dll. It is a factory method for `ISimpleLPR` objects.

**Returns:** A pointer to a `ISimpleLPR` object. The returned `ISimpleLPR` object must be de-allocated by calling its `release` method.

**Remarks:** Since no .lib file is provided in the SDK, `SimpleLPR2.dll` must be loaded dynamically.

5.2 Structures

5.2.1 Rect

This structure represents a rectangle.

```c
struct Rect {
    _int32 left;
    _int32 top;
    _int32 width;
    _int32 height;
};
```

**Members**

- `left` Leftmost coordinate of the rectangle.
- `top` Topmost coordinate of the rectangle.
- `width` Rectangle width.
- `height` Rectangle height.

5.2.2 Element

It stores the LPR results of an individual character in a license plate.

```c
struct Element {
    wchar_t glyph;
    _REAL_T fConfidence
    Rect boundingBox;
};
```

**Members**

- `glyph` Unicode representation of the character.
'Goodness' of the recognition. Its range is 0 to 1 and can be used to rank candidates although it should not be regarded as a probability. In general, a $2x$ goodness value is not twice as good as $x$. See the section on LPR for more detailed information on confidence values.

**BoundingBox** Bounding rectangle of the character, in pixel coordinates.

### 5.2.3 VersionNumber

This structure holds the four numbers that comprise the SimpleLPR version number.

```c
struct Rect {
    unsigned __int32 A;
    unsigned __int32 B;
    unsigned __int32 C;
    unsigned __int32 D;
};
```

**Members**

- **A** First element of the of SimpleLPR_Native.dll product number.  
- **B** Second element of the of SimpleLPR_Native.dll product number.  
- **C** Third element of the of SimpleLPR_Native.dll product number.  
- **D** Fourth element of the of SimpleLPR_Native.dll product number.

### 5.3 Interfaces

#### 5.3.1 IReferenceCounted

This interface constitutes the base for all interfaces. It manages object life cycles by means of reference counting. All factory methods in this library return pointers to objects with their reference count set to 1 or more.

It is advisable to call the `addRef` method every time a pointer alias is created. Before an object pointer goes out of scope its `release` method should be called. When an object reference count reaches zero the object is destroyed.

```c
struct IReferenceCounted {
    virtual void addRef( void ) throw () = 0;
    virtual void release( void ) throw () = 0;
};
```

**Methods**

- **virtual void addRef( void ) throw () = 0;**

*Description:* Increments an object reference count by one.

- **virtual void release( void ) throw () = 0;**
Description: Decrement an object reference count by one. When it reaches 0 the object is destroyed.

5.3.2 IErrorInfo

This class conveys an error code and a description. Every time an error occurs an IErrorInfo object is created and kept in thread local storage (TLS). To retrieve it use the ISimpleLPR::lastError_get method.

```cpp
struct IErrorInfo : public IReferenceCounted
{
    virtual _HRESULT errorCode_get() const throw () = 0;
    virtual const wchar_t * description_get() const throw () = 0;
};
```

Methods

virtual _HRESULT errorCode_get() const throw () = 0;

Description: Returns a COM like HRESULT error code.

virtual const wchar_t * description_get() const throw () = 0;

Description: Returns a textual description of the error.

5.3.3 ICandidate

Encapsulates a license plate candidate.

```cpp
struct ICandidate : public IReferenceCounted
{
    virtual const wchar_t *text_get() const throw () = 0;
    virtual const wchar_t *country_get() const throw () = 0;
    virtual _REAL_T confidence_get() const throw () = 0;
    virtual bool brightBackground_get() const throw () = 0;
    virtual _SIZE_T numElements_get() const throw () = 0;
    virtual bool element_get( _SIZE_T id, /*[out]*/Element &rElem ) const throw () = 0;
};
```

Methods

virtual const wchar_t *text_get() const throw () = 0;

Description: Returns the Unicode representation of the license plate string. Separators are represented as white space.

virtual const wchar_t *country_get() const throw () = 0;

Description: Returns the country code in string form.

virtual _REAL_T confidence_get() const throw () = 0;
**Description:** Returns the overall 'goodness' of the recognition. Currently it is calculated as the minimum goodness value of all individual characters in the license plate.

```cpp
virtual bool brightBackground_get() const throw () = 0;
```

**Description:** true if the license plate features dark text on a light background. false if otherwise.

```cpp
virtual _SIZE_T numElements_get() const throw () = 0;
```

**Description:** Number of components in the license plate.

```cpp
virtual bool element_get( _SIZE_T id, /*[out]*/Element &rElem
) const throw () = 0;
```

**Description:** Information about the individual chars that make up the license plate. They are listed in the same order as they appear in the text string. To know the physical layout of the license plates use the `Element::bbox` field.

### 5.3.4 ICandidates

Encapsulates a collection of license plate candidates.

```cpp
struct ICandidates : public IReferenceCounted
{
    virtual _SIZE_T numCandidates_get() const throw () = 0;
    virtual ICandidate *candidate_get( _SIZE_T id ) const throw () = 0;
};
```

**Methods**

```cpp
virtual _SIZE_T numCandidates_get() const throw () = 0;
```

**Description:** Returns the number of elements in the collection.

```cpp
virtual ICandidate *candidate_get( _SIZE_T id ) const throw () = 0;
```

**Description:** Returns a candidate object given its index.

**Parameters**

**Input**

- *Id:* Candidate identifier. Must be <= `numCandidates_get()`

**Returns:** A pointer to the selected candidate object.

**Remarks:** The returned `ICandidate` object must be de-allocated by calling its `release` method.
5.3.5 IProcessor

Encapsulates the LPR functionality of SimpleLPR 2. This class is not multi-threaded and, therefore, each thread should use a different IProcessor instance.

```cpp
struct IProcessor : public IReferenceCounted
{
    virtual ICandidates *analyze_C3( const void *pcvImgData,
                                       _SIZE_T widthStep,
                                       _SIZE_T width,
                                       _SIZE_T height,
                                       _SIZE_T maxCharHeight,
                                       _REAL_T fWeight0,
                                       _REAL_T fWeight1,
                                       _REAL_T fWeight2 ) throw () = 0;

    virtual ICandidates *analyze( const void *pcvImgData,
                             _SIZE_T widthStep,
                             _SIZE_T width,
                             _SIZE_T height,
                             _SIZE_T maxCharHeight ) throw () = 0;

    virtual ICandidates *analyze( const wchar_t * pcwsImgPath,
                             _SIZE_T maxCharHeight ) throw () = 0;
};
```

**Methods**

```cpp
virtual ICandidates *analyze_C3( const void *pcvImgData,
                                       _SIZE_T widthStep,
                                       _SIZE_T width,
                                       _SIZE_T height,
                                       _SIZE_T maxCharHeight,
                                       _REAL_T fWeight0,
                                       _REAL_T fWeight1,
                                       _REAL_T fWeight2 ) throw () = 0;
```

**Description:** Looks for license plate candidates in a memory buffer containing a 3-channel 8 bit/channel color image stored in pixel order. Every pixel in the source image is internally converted to gray scale according to the following formula:

\[ L = fWeight0 \times C0 + fWeight1 \times C1 + fWeight2 \times C2 \]

For instance, to convert a RGB image to gray scale according the standard for the NTSC CRT the value of the weights should be:

- Red: \( fWeight0 = 0.299 \)
- Green: \( fWeight1 = 0.587 \)
- Blue: \( fWeight2 = 0.114 \)

**Parameters**

**Input**
**plmgData**: Pointer to the first image row. The image must be a 3-channel 8 bit/channel color image stored in pixel order and down. The top row of the image is the first row in memory, followed by next row down.

**widthStep**: Distance in bytes between starts of consecutive rows in the source image.

**width**: Image width in pixels.

**height**: Image height in pixels.

**maxCharHeight**: Maximum height in pixels of the characters in the license plate.

**fWeight0**: Weight of the first channel.

**fWeight1**: Weight of the second channel.

**fWeight2**: Weight of the third channel.

**Returns**: A pointer to an ICandidates collection containing all license plate candidates. If something goes wrong it returns a NULL pointer, use ISimpleLPR::lastError_get to get the error information.

**Remarks**: This method is not multi-threaded. The returned ICandidates object must be de-allocated by calling its release method.

```cpp
virtual ICandidates *analyze( const void *pcvImgData,
                               _SIZE_T widthStep,
                               _SIZE_T width,
                               _SIZE_T height,
                               _SIZE_T maxCharHeight ) throw ()
= 0;
```

**Description**: Looks for license plate candidates in a memory buffer containing an 8 bit gray scale image.

**Parameters**

**Input**

**plmgData**: Pointer to the first image row. The image must be 8 bit gray scale and top down. The top row of the image is the first row in memory, followed by the next row down.

**widthStep**: Distance in bytes between starts of consecutive rows in the source image.

**width**: Image width in pixels.

**height**: Image height in pixels.

**maxCharHeight**: Maximum height in pixels of the characters in the license plate

**Returns**: A pointer to an ICandidates collection containing all license plate candidates. If something goes wrong it returns a NULL pointer, use ISimpleLPR::lastError_get to get the error information.

**Remarks**: This method is not multi-threaded. The returned ICandidates object must be de-allocated by calling its release method.

```cpp
virtual ICandidates *analyze( const wchar_t * pcwsImgPath,
                               _SIZE_T maxCharHeight ) throw ()
= 0;
```

**Description**: Looks for license plate candidates in an image in a .jpg, .png, .tif or .bmp file. The images can be either 24 bit RGB or 8 bit gray scale.

**Parameters**

**Input**
`pcwsImgPath`: Path to a file containing a 24 bit RGB or 8 bit gray scale image.

`maxCharHeight`: Maximum height in pixels of the characters in the license plate

**Returns**: A pointer to an `ICandidates` collection containing all license plate candidates. If something goes wrong it returns a NULL pointer, use `ISimpleLPR::lastError_get` to get the error information.

**Remarks**: This method is not multi-threaded. The returned `ICandidates` object must be de-allocated by calling its `release` method.

### 5.3.6 ISimpleLPR

Encapsulates the `SimpleLPR` 2 engine.

```c++
struct ISimpleLPR : public IReferenceCounted {
    virtual _SIZE_T numSupportedCountries_get() const throw () = 0;
    virtual bool countryCode_get( _SIZE_T id,
        /*[out]*/const wchar_t *&rpcwsCode ) const throw () = 0;
    virtual bool countryCode_get( const wchar_t *id,
        /*[out]*/_REAL_T &rfWeight ) const throw () = 0;
    virtual bool countryWeight_set( _SIZE_T id,
        _REAL_T fWeight ) throw () = 0;
    virtual bool countryWeight_set( const wchar_t *id,
        _REAL_T fWeight ) throw () = 0;
    virtual bool realizeCountryWeights() throw () = 0;
    virtual IErrorInfo *lastError_get( bool bClear = true ) throw () = 0;
    virtual IProcessor *createProcessor() throw () = 0;
    virtual bool productKey_set( const wchar_t *productKeyPath ) throw () = 0;
    virtual bool productKey_set( const void *key, _SIZE_T keySize ) throw () = 0;
    virtual bool versionNumber_get( /*[out]*/SIMPLELPR_VersionNumber &rVersion ) throw () = 0;
};
```

#### Methods

- `virtual _SIZE_T numSupportedCountries_get() const throw () = 0;`

  **Description**: Returns the number of supported countries.

- `virtual bool countryCode_get( _SIZE_T id, /*[out]*/const wchar_t * &rpcwsCode ) const throw () = 0;`

  **Description**: Given a country index it returns its string identifier.

  **Parameters**

  - **Input**
id: The country index. 0 <= id <= numSupportedCountries_get() - 1.

Output:
rpcwsCode:: The country Unicode string identifier.

Returns: true if the method succeeded, false otherwise. In the later case use ISimpleLPR::lastError_get to obtain the error information.

virtual bool countryWeight_get( _SIZE_T id,
                             /*[out]*/_REAL_T &rfWeight )
const throw () = 0;

Description: Given a country index it returns the relative country weight. Weights are used to break ties when a candidate can belong to multiple countries.

Parameters:
Input:
Id: The country index. 0 <= id <= numSupportedCountries_get() - 1.

Output:
rfWeight:: The relative weight of the country.

Returns: true if the method succeeded, false otherwise. In the later case use ISimpleLPR::lastError_get to obtain the error information.

virtual bool countryWeight_get( const wchar_t *id,
                             /*[out]*/_REAL_T &rfWeight )
const throw () = 0;

Description: Given a country string identifier it returns the relative country weight. Weights are used to break ties when a candidate can belong to multiple countries.

Parameters:
Input:
Id: The country string identifier. See countryCode_get.

Output:
rfWeight:: The relative weight of the country.

Returns: true if the method succeeded, false otherwise. In the later case use ISimpleLPR::lastError_get to obtain the error information.

virtual bool countryWeight_set(_SIZE_T id,
                             _REAL_T fWeight) throw () = 0;

Description: Given a country index it sets the country relative weight. Weights are used to break ties when a candidate can belong to multiple countries.

Parameters:
Input:
id: The country index. 0 <= id <= numSupportedCountries_get() - 1.
fWeight:: The desired country weight. fWeight >= 0.

Returns: true if the method succeeded, false otherwise. In the later case use ISimpleLPR::lastError_get to obtain the error information.

Remarks: This method is not multi-threaded. Weight must be >= 0. Use a zero weight to effectively disable a specific country.
virtual bool realizeCountryWeights() throw () = 0

Description: Rebuilds the internal country verification lookup tables based on which countries are enabled and their relative weights. Call it once you have finished configuring country weights.

Returns: true if the method succeeded, false otherwise. In the later case use ISimpleLPR::lastError_get to obtain the error information.

Remarks: This method is not multi-threaded. Depending on the countries selected this method can be time consuming. After this method execution all existing and new IProcessor instances will start using the new weights. Avoid calling this method when another thread is executing IProcessor::analyze.

virtual IErrorInfo *lastError_get( bool bClear = true ) throw ();

Description: Returns an IErrorInfo object that describes the latest error occurred.

Parameters

Input

bClear: If true the error state will be cleared after this call.

Returns: An IErrorInfo object that describes the latest error or NULL if no error has occurred since application startup or the last call to lastError_get with bClear set to true.

Remarks: This method is multi-threaded. In particular each thread maintains a TLS slot with error state so threads can be independent from each other.

virtual IProcessor *createProcessor() throw () = 0;

Description: Creates a new IProcessor object.

Returns: The newly created IProcessor instance, or NULL if the method failed. Use ISimpleLPR::lastError_get instance, or the last call to lastError_get with bClear set to true.

Remarks: This method is multi-threaded. For this method to succeed, either the product must be within the evaluation period or a valid product key must be supplied using productKey_set. The returned IProcessor object must be de-allocated by calling its release method.

virtual bool productKey_set( const wchar_t *productKeyPath ) throw () = 0;

Description: Sets the product key from a license file.

Parameters

Input

productKeyPath: Path to the product key file.

Returns: true if the method succeeded, false otherwise. In the later case use ISimpleLPR::lastError_get to obtain the error information.

virtual bool productKey_set( const void *key, _SIZE_T keySize ) throw () = 0;

Description: Sets the product key from a memory buffer.
Parameters

Input
key: Pointer to the memory buffer.
keySize: keySize in bytes.

Returns: true if the method succeeded, false otherwise. In the later case use ISimpleLPR::lastError_get to obtain the error information.

virtual bool versionNumber_get(
    /*[out]*/SIMPLELPR_VersionNumber &rVersion ) throw () = 0;

Description: Gets the version number of SimpleLPR2.Native.dll.
Parameters
Output:
Returns: true if the method succeeded, false otherwise. In the later case use ISimpleLPR::lastError_get to obtain the error information.
6 .NET Interface Reference

6.1 SimpleLPR

SimpleLPR 2 factory class.

6.1.1 Methods

6.1.1.1 Setup

Creates a ISimpleLPR object.

6.1.1.1.1 Return Value

Return Value: A ISimpleLPR instance.

6.2 ISimpleLPR

Encapsulates the SimpleLPR 2 engine.

6.2.1 Properties

6.2.1.1 numSupportedCountries

Return Value: Number of supported countries.

6.2.1.2 versionNumber

Return Value: Gets the version number of SimpleLPR2_native.dll.

6.2.2 Methods

6.2.2.1 set_productKey(System.Byte[])]

Sets the product key from a memory buffer.

6.2.2.1.1 Parameters

productKey: Byte array containing the product key.

6.2.2.2 set_productKey(System.String)

Sets the product key from a license file.

6.2.2.2.1 Parameters

productKeyPath: Path to the product key file.
6.2.2.3 createProcessor

Creates a new IProcessor object.

6.2.2.3.1 Return Value

Return Value: The newly created IProcessor instance.

6.2.2.4 realizeCountryWeights

Rebuilds the internal country verification lookup tables based on which countries are enabled and their relative weights. Call it once you have finished configuring country weights.

6.2.2.5 set_countryWeight(System.String,System.Single)

Sets the country relative weight. Weights are used to break ties when a candidate can belong to multiple countries.

6.2.2.5.1 Parameters

id: The country string identifier. See get_countryCode(System.UInt32).

val: The desired country weight. val >= 0

6.2.2.6 get_countryWeight(System.String)

Given a country string identifier it gets the country relative weight. Weights are used to break ties when a candidate can belong to multiple countries.

6.2.2.6.1 Parameters

id: The country string identifier. See get_countryCode(System.UInt32).

6.2.2.6.2 Return Value

Return Value: The relative weight of the country.

6.2.2.7 set_countryWeight(System.UInt32,System.Single)

Sets the country relative weight. Weights are used to break ties when a candidate can belong to multiple countries.

6.2.2.7.1 Parameters

id: The country index. 0 <= id <= numSupportedCountries - 1

val: The desired country weight. val >= 0
6.2.2.8 get_countryWeight(System.UInt32)

Given a country index it gets the country relative weight. Weights are used to break ties when a candidate can belong to multiple countries.

6.2.2.8.1 Parameters

id: The country index. 0 <= id <= numSupportedCountries - 1

6.2.2.8.2 Return Value

Return Value: The relative weight of the country.

6.2.2.9 get_countryCode(System.UInt32)

Given a country index it returns its string identifier.

6.2.2.9.1 Parameters

id: The country index. 0 <= id <= numSupportedCountries - 1

6.2.2.9.2 Return Value

Return Value: The country string identifier.

6.3 IProcessor

Provides access to the license plate recognition functionality of SimpleLPR.

This class is not multi-threaded and, therefore, each thread should use a different IProcessor instance.

6.3.1 Methods

6.3.1.1 analyze(System.String,System.UInt32)

Looks for license plate candidates in an image loaded from a .jpg, .png, tif or .bmp file. The images can be either 24 bit RGB or 8 bit gray scale.

imgPath: Path to a file containing a 24 bit RGB or 8 bit gray scale image.

maxCharHeight: Maximum height in pixels of the characters in the license plate.

Return Value: List of Candidate containing all license plate candidates.

6.3.1.2 analyze(System.IntPtr,System.UInt32,System.UInt32,System.UInt32,System.UInt32)

Looks for license plate candidates in a memory buffer containing a 8 bit gray scale image.
6.3.1.2.1 Parameters

pImgData: Pointer to the first image row. The image must be 8 bit gray scale and top down: the top row of the image is the first row in memory, followed by the next row down.

widthStep: Distance in bytes between starts of consecutive rows in the source image.

width: Image width in pixels.

height: Image height in pixels.

maxCharHeight: Maximum height in pixels of the characters in the license plate.

6.3.1.2.2 Return Value

Return Value: List of Candidate containing all license plate candidates.

6.3.1.3 analyze_C3(System.IntPtr, uint, uint, uint, float, float, float)

Looks for license plate candidates in a memory buffer containing a 3-channel 8 bit/channel color image stored in pixel order. Every pixel in the source image is internally converted to gray scale according to the following formula:

\[ L = f\text{Weight}_0 \times C0 + f\text{Weight}_1 \times C1 + f\text{Weight}_2 \times C2. \]

For instance, to convert a RGB image to gray scale according the standard for the NTSC CRT the value of the weights should be:

Red: \( f\text{Weight}_0 = 0.299 \) Green: \( f\text{Weight}_1 = 0.587 \) Blue: \( f\text{Weight}_2 = 0.114 \).

6.3.1.3.1 Parameters

pImgData: Pointer to the first image row. The image must be a 3-channel 8 bit/channel color image stored in pixel order and top down: the top row of the image is the first row in memory, followed by the next row down.

widthStep: Distance in bytes between starts of consecutive rows in the source image.

width: Image width in pixels.

height: Image height in pixels.

maxCharHeight: Maximum height in pixels of the characters in the license plate.

fWeight0: Weight of the first channel.

fWeight1: Weight of the second channel.

fWeight2: Weight of the third channel.
6.3.1.3.2 Return Value

Return Value: List of Candidate containing all license plate candidates.

6.4 Candidate

Encapsulates a license plate candidate.

6.4.1 Fields

6.4.1.1 elements

Information about the individual chars that make up the license plate. They are listed in the same order as they appear in the text string. To know the physical layout use the bbox field.

6.4.1.2 brightBackground

True if the license plate features dark text on a light background. False if otherwise.

6.4.1.3 confidence

Overall ‘goodness' of the recognition. Currently it is calculated as the minimum goodness value of all individual characters in the license plate. See confidence.

6.4.1.4 country

Country code string.

6.4.1.5 text

Unicode representation of the license plate string. Separators are represented as white space.

6.5 Element

Encapsulates a candidate character in a license plate.

6.5.1 Fields

6.5.1.1 bbox

Bounding box of the character, in pixel coordinates.
6.5.1.2 confidence

'Goodness' of the recognition. Its range is 0 to 1 and can be used to rank candidates although it should not be regarded as a probability. In general, a 2x goodness value is not twice as good as x.

6.5.1.3 glyph

Unicode representation of the character.
